Save money and increase reliability.

Reduce momentary outages and truck rolls with S&C’s self-powered, electronically controlled single-phase recloser.
A better solution for overhead lateral circuit protection at 15 kV and 25 kV

Utilities need a better option for their fault-protection strategy.

More than 80% of transient faults on overhead distribution circuits occur on laterals. A utility’s lateral-protection strategy could either be causing more momentary outages or more truck rolls.

TRUCK ROLLS CAN EXCEED $1,000

With all the laterals on a utility’s system, truck-roll costs can add up to millions of dollars every year.

Over the years, utilities have dealt with lateral protection a couple of ways.

Some utilities use a “fuse-blowing” philosophy: The substation feeder breaker is properly coordinated with the lateral fuse so the fuse, not the breaker, will clear any downstream fault within its rating, but not the breaker. Customers on the lateral experience sustained service interruption—even for a transient fault, as shown in Figure 1. And the utility must deal with the high cost of service calls to replace lateral fuses.

Other utilities use a “fuse-saving” philosophy: The first trip of the substation feeder breaker is intentionally coordinated so the breaker operates faster than the lateral fuse to clear a fault downstream of the lateral fuse. The second trip of the breaker is slower so if the fault is still present, the lateral fuse will operate to clear it. All customers on the feeder experience a momentary interruption for all faults, as shown in Figure 2.

TripSaver II reclosers combine the best of fuse-saving and fuse-blowing and improve reliability.

S&C’s TripSaver II Cutout-Mounted Recloser keeps the power on and avoids truck rolls. A lateral-reclosing strategy ensures transient faults do not result in a sustained interruption and other laterals on the feeder are not “blinking.”

Power can be restored automatically for transient faults, avoiding a sustained outage or the need for a truck roll. Utilities will see immediate improvement in the frequency of sustained outages on their system.

Another benefit of a lateral-reclosing strategy is it moves the reclosing closer to the problem, allowing only the faulted lateral to experience a blink. See Figure 3 on page 3.
The TripSaver II recloser’s operating sequence

The TripSaver II Cutout-Mounted Recloser supports up to three reclosing operations (four tripping operations in total) before it drops open. Multiple varieties of time-current characteristic (TCC) curves are available. The duration of the open interval between tripping operations is user-configurable. It has a range from 0.5 seconds to 5 seconds. An option with an extended open interval of up to 30 seconds is also available.

The vacuum interrupter resets 2 seconds after the TripSaver II recloser drops open. The operator can then manually close the TripSaver II recloser back in to the mounting after the repair has been made.

In instances when a transient fault clears before the TripSaver II recloser reaches the end of its operating sequence, the recloser will revert to its first TCC curve after its sequence reset timer expires. The sequence reset time is also user-configurable, and it has a range from 0.5 seconds to 1,000 seconds.

How the TripSaver II recloser works for a transient fault

Consider a transient fault downstream of the TripSaver II Cutout-Mounted Recloser. Using its fast TCC curve, the TripSaver II recloser opens, as shown in Figure 3. Only customers served from the lateral downstream of the TripSaver II recloser experience a momentary interruption.

After the open interval, the TripSaver II recloser recloses, restoring power to customers served from the lateral downstream. Because the fault was transient and cleared, further tripping operations aren’t needed. The TripSaver II recloser reverts to its first TCC curve after the sequence reset time.

How the TripSaver II recloser works for a persistent fault

Consider a persistent fault downstream of the TripSaver II recloser. Because the fault is persistent, the TripSaver II Cutout-Mounted Recloser performs further tripping operations per the specified TCC curves. For utilities using a “fuse-saving” philosophy, the TripSaver II recloser drops open at the end of its operating sequence in the same manner as a standard fuse cutout—providing visual indication the faulted lateral has been isolated, as shown in Figure 4. The vacuum interrupter resets 2 seconds after the TripSaver II recloser drops open. The recloser may then be manually closed back in to the mounting by the operator when the fault has been repaired.

Figure 3. The TripSaver II recloser opens.

Figure 4. The TripSaver II recloser drops open.
**Type XS Fuse Cutout Mounting**—With its birdproof design and composite polymer silicone or porcelain insulators, Type XS Fuse Cutout Mountings provide a higher level of characteristics than ANSI distribution cutout standards. TripSaver II reclosers can be installed in new or existing production ("R10" or "R11") mountings.

**Parallel-groove connector**—Fabricated of tin-plated cast red brass (For ease of connection, the recloser accommodates two conductors, even of unlike size.)

**Attachment hooks**—These allow the TripSaver II recloser to be manually opened using Loadbuster®—The S&C Loadbreak Tool.

**Bumper and retainer**—Unique to TripSaver II reclosers, this spring-loaded retainer and bumper dampen impact on closing, reducing the possibility of bounce-back.

**Vacuum fault interrupter**—Located in the upper housing, it quietly contains and interrupts the fault without exhaust or sparking.

**Trunnion**—High-strength cast bronze, silver-plated (Surfaces around the trunnion bear on broad hinge surfaces to keep the TripSaver II recloser in alignment during closing. Its special shape facilitates easy removal and reduces vibration.)

**Tag-clip option**—This allows crews to tag the TripSaver II recloser in a highly visible location, required to communicate nonstandard conditions.

**Mode-selector lever**—This allows crews working downstream of the TripSaver II recloser to select an automatic reclosing or nonreclosing operation.

**LCD screen**—This displays user-configurable TripSaver II recloser status automatically, giving visibility for any crew member (no laptop needed).

**Internal communications**—This allows the user to interact with the TripSaver II recloser wirelessly to handle programming and interrogation sessions without the need for a crew to be present.
Remote Drop Open
When configured with a TripSaver® II Communications Gateway, the new Remote Drop Open feature will allow a “drop open” SCADA command to be sent via DNP 3.0 through the communications gateway to the TripSaver II recloser.

Sequence Coordination
The Sequence Coordination feature maintains proper coordination between the TripSaver II Cutout-Mounted Recloser and downstream reclosers. If a fault is cleared by a downstream recloser, the TripSaver II recloser will shift to a user-configured (usually slower) time-current characteristic curve before fault testing. The TripSaver II recloser will maintain its sequence coordination setting until the Coordination Reset timer expires.

Sectionalizing Feature
The TripSaver II recloser features a Sectionalizing mode in both 4-kA and 6.3-kA-rated models. When enabled, the recloser will operate as a sectionalizer over a user-specified range of fault currents when the source-side circuit breaker or recloser trips faster than the TripSaver II recloser does. It counts the number of operations of the source-side circuit breaker or recloser and drops open after a user-specified number of counts.

Inrush-Restraint Feature
The TripSaver II Cutout-Mounted Recloser has a novel Magnetizing Inrush-Restraint feature that is always on, measuring second-harmonic current to distinguish fault current from inrush current. If inrush current is detected, the TripSaver II recloser will not trip. The Inrush-Restraint feature facilitates lower minimum pickup currents down to 5 amperes.

Local Manual Open Feature
The Local Manual Open feature removes the requirement to use the S&C Loadbuster tool for loadbreaking by providing a manual operation sequence that commands the TripSaver II recloser to open the vacuum-interrupter contacts and drop open.

NON-RECLOSE TCC Curves
In earlier firmware versions, when the TripSaver II recloser NON-RECLOSE lever was in the Down (activated) position, the instantaneous TCC curve was automatically activated. The new Non-Reclose feature allows the user to configure three TCC curves from the library for use during Non-Reclose mode. These new TCC curves are named the Standard Non-Reclose TCC curve, the Post Fault Non-Reclose TCC curve, and the Cold Wake-up Non-Reclose TCC curve. The curve that will be active is dependent on the load or fault condition prior to Non-Reclose mode activation or when a dropout previously occurred. The TCC curve selection will occur automatically without requiring the operator to manually select the appropriate settings. Non-Reclose (NR) mode can also be set remotely (Remote Non-Reclose (R-NR) mode) by a DNP 3.0 command when the TripSaver II recloser is properly configured with the gateway and transceiver.

Gang Operation Feature
When multiple TripSaver II reclosers are properly configured together with the TripSaver II Communications Gateway, the Gang Operation feature allows any TripSaver II recloser that responds to a protection drop-open event or to a Local Manual Open drop-open event to signal the gateway to send Drop-open commands to the other configured TripSaver II reclosers. See Figure 5.

When a permanent fault occurs...

The TripSaver II recloser isolates the fault and sends a drop-open notification to the gateway...

The gateway sends a Drop-open command to the remaining TripSaver II reclosers...

TripSaver® II Communications via Gateway
The TripSaver II Cutout-Mounted Recloser offers a Remot
Communication option using field-area networks already
built for SCADA, advanced metering infrastructure,
or distribution automation. See Figure 6. The remote
communication provides the following data as DNP 3
functionality:
- Unsolicited alerts
- GPS time and coordinates
- Device heartbeat
- Remote mode-change capability

TripSaver II reclosers with the Extended Open-Interval
feature and a communications gateway are required.

The communications gateway is a padlockable, weather-
proof enclosure mounted directly on a utility pole. It includes
a configurable gateway controller and provision for a radio of
the customer’s choice connected via an Ethernet or a serial
port. The gateway uses control power from an overhead
transformer and includes an optional backup battery for
riding through a loss of control power to the
communications gateway.

All gateway configurations include a door alarm sys-
tem and an integrated multi-band antenna capable of
supporting GPS, cellular radios, and 900-MHz ISM and
900-MHz MAS radios.

TripSaver® II Service Center
Configuration Software
The TripSaver II provides customers with flexibility to
reconfigure their reclosers and read event logs using
S&C TripSaver II Service Center Configuration Software.
See Figure 7. The most-recent release includes TripSaver II
Service Center Configuration Software version 1.8 and the
USB transceiver version 1.6, which is required for use with
the new configuration software. The combination of the new
transceiver and software is fully backward-compatible with
all previous versions of TripSaver II reclosers and snapshot
files and should be used in place of any previous versions.

Service Center Configuration Kit
This portable configuration kit also includes a universal
power supply for the TripSaver II recloser and a USB trans-
ceiver for a computer to communicate with the recloser.

The intuitive graphical user interface makes the
configuration process quick and easy. The software also
allows users to view status-related information, read event
logs, and perform functional tests.
